

## Synthesis And Infrared Study Of New Tungstato Polynuclear Cadmium (ii) And Mercury (ii) Complexes

### Synthèse et étude infrarouge de nouveaux complexes tungstato polynucléaires du cadmium (ii) et du mercure (imi)

DE BARROS Dinora<sup>1</sup>, DIALLO Waly<sup>1</sup> And DIOP Libasse<sup>1\*</sup>

#### **Abstract :**

Eleven new polynuclear tungstato  $MX_2$ (X=Cl, Br) adducts were synthesized and studied by infrared spectroscopy. The suggested structures are discrete, the tungstate anion behaving as a bi-, tri- and tetrachelating ligand.

#### **Résumé :**

Onze nouveaux complexes tungstato polynucléaires ont été synthétisés et étudiés par spectroscopie infrarouge. Les structures proposées sont discrètes, l'ion tungstate se comportant comme un ligand bi-, tri- et tétrachélatant.

#### **Mots clés :**

Complexes tungstato polynucléaires, anion tungstate, structure discrète, infrarouge, ligand bichélatant trichélatant, tétrachélatant.

#### **Key words :**

Polynuclear tungstato adducts, tungstate anion, infrared, discrete structures, bichelatant, trichelatant, tetrachelatant ligand.

## 1 - Introduction

The main results on the coordination chemistry of oxyanions have been reviewed by Hathaway [1]. The coordinating behaviour of the perchlorate anion has been studied by Pascal and coll [2-4]. The coordinating behaviour polytungstate anions has been studied [5-7], some results have also been obtained on tungstato complexes [8, 9].

Since many years our laboratory has been involved in research dealing with the coordinating ability of tetrahedral and pyramidal oxyanions [10-13].

In the aim of getting more informations on the behaviour of tungstate ions ( $\text{WO}_4^{2-}$  and  $\text{HWO}_4^-$ ), we have initiated the study of the interactions between salts such as  $(\text{Me}_4\text{N})_2\text{WO}_4 \cdot \text{Me}_4\text{NHWO}_4 \cdot 2\text{H}_2\text{O}$  or  $(\text{Et}_4\text{N})_2\text{WO}_4 \cdot \text{Et}_4\text{NHWO}_4 \cdot 4\text{H}_2\text{O}$  and the dihalides of Cd and Hg. The adducts obtained have been studied by infrared spectroscopy and structures suggested on the basis of the infrared data.

## 2. - Experimentals

**2.1 - Synthesis Of The Tungstic Acid Salts**  
 $(\text{Me}_4\text{N})_2\text{WO}_4 \cdot \text{Me}_4\text{NHWO}_4 \cdot 2\text{H}_2\text{O}$  ( $L_1$ ) and  $(\text{Et}_4\text{N})_2\text{WO}_4 \cdot \text{Et}_4\text{NHWO}_4 \cdot 4\text{H}_2\text{O}$  ( $L_2$ ) were prepared by mixing water solutions of the appropriate tetraalkylammonium hydroxyde (MERCK) with tungstic acid  $\text{H}_2\text{WO}_4$  97 % (MERCK). The white powder obtained after solvent evaporation, is recrystallized from EtOH, washed with éther and kept under  $\text{P}_2\text{O}_5$ .

## 2.2 - Synthesis Of Complexes

All the compounds were obtained as white precipitates on mixing both ethanolic solutions of  $\text{MX}_2$  ( $\text{M} = \text{Cd}, \text{Hg}$ ;  $\text{X} = \text{Cl}, \text{Br}$ ) with the quaternary ammonium salt ( $L_1$ ) and ( $L_2$ ) in defined ratio (ligand/ $\text{MX}_2$ ). The precipitates were non stirred or stirred during more than two hours, filtered and washed with hot ethanol.

The analytical data are reported in table I. Elemental analyses were performed by the Analytical Laboratory of the Department of Inorganic and Analytical Chemistry (University of Padova, Italy) and the CNRS « Service Central d'Analyses », Vernaison, France.

The infrared spectra were scanned on a 580 Perkin-Elmer spectrometer as nujol mulls ( $4000-200 \text{ cm}^{-1}$ ) or a Bruker FTIR ( $600-50 \text{ cm}^{-1}$ ) spectrometer using CsI or polyethylene plates.

### 3. - Results And Discussion

The infrared data of the adducts are presented in table II with the assignments based on literature data [8]

A -  $(\text{Me}_4\text{N})_2\text{WO}_4 \cdot 2 \text{MBr}_2$  (M=Hg, Cd) (S<sub>1</sub> and S<sub>2</sub>)

The absence of v<sub>2</sub> (symmetrical bending mode) is an indication of Td symmetry for the tungstate ion according to Group Theory. The intense envelope of v<sub>3</sub> (antisymmetrical stretching mode) with many components (due to crystal effects) is consistent with Td symmetry for the tungstate ion. The suggested structure for S<sub>1</sub>

is a discrete one with a bichelating tungstate anion, the environment around the mercury atom being tetrahedral (**figure I**). In the bichelation all the oxygen atoms are involved.

**Fig I**

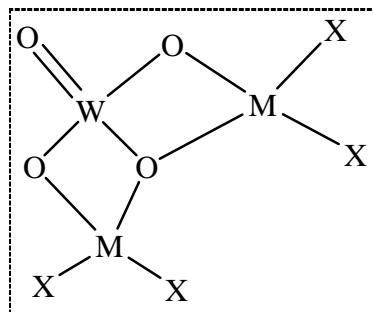

The splitting of v<sub>4</sub> into three bands (2A' + A'') and the appearance of v<sub>2</sub> as two bands

$(A' + A'')$  on the infrared spectrum of  $S_2$  are consistent with a tungstate ion in  $C_s$  symmetry. The suggested structure for  $S_2$  is discrete with a tri-oxygen atoms bichelating tungstate anion (**figure II**).

**Fig II**

Considering the spectrum of  $S_3$ , the non splitting of  $\nu_3$  and  $\nu_4$  is an indication of  $Td$  sym-metry for the tungstate anions. The suggested structure for these complexes is discrete with a central metal cation bichelated by two tungstate anions linked to one molecule of  $HgBr_2$  (**figure III**), the environment around the metal being tetrahedral as predicted by the Ligand Field Theory when extra ligand addition does not occur.

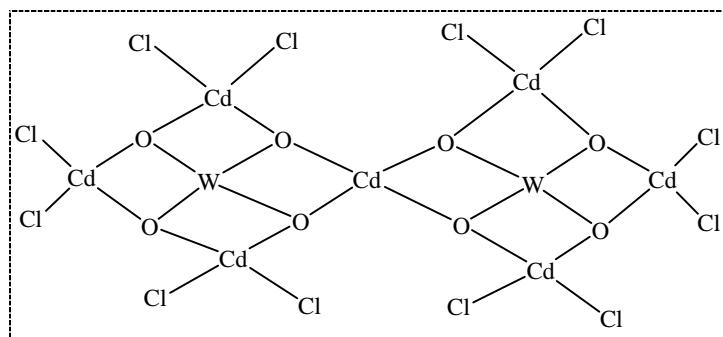

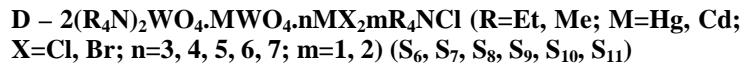

**Fig III : C –  $(Et_4N)_2WO_4 \cdot MWO_4 \cdot nMCl_2 \cdot mEt_4NCl$  (M=Cd, Hg) (n=4, 6; m=0, 1) ( $S_4, S_5$ )**

The non splitting of  $\nu_4$  on the spectrum of  $S_4$  indicates  $Td$  symmetry for the tungstate anion and allows to consider  $S_4$  as a central  $M^{2+}$  cation chelated by two  $[WO_4(MX_2)_2]^{2-}$  complex-anions (**figure IVa**); the additional chloride ion can be linked to the central  $Hg^{2+}$ , the environment around the metal being tetrahedral.

**Fig IVa**

In the case of  $S_5$ , the two complex-anions chelating the central metal are  $[WO_4(MX_2)_3]^{2-}$  (**figure IVb**).

The appearance of  $\nu_1$  as a trace or weak on the infraed spectra allows to consider  $Td$  symmetry for the tungstate ion. These complexes can be considered as a central  $M^{2+}$  ion surrounded by three  $[WO_4 \cdot HgCl_2]^{2-}$  in  $S_6$  and  $S_7$ , two  $[WO_4 \cdot (CdCl_2)_2]^{2-}$  and one  $[WO_4 \cdot CdCl_2]^{2-}$  in  $S_9$ , one  $[WO_4 \cdot (CdBr_2)_2]^{2-}$  and two  $[WO_4(CdBr_2)]^{2-}$  in  $S_{10}$ , three  $[WO_4(HgCl_2)]^{2-}$  in  $S_8$ , one  $[WO_4 \cdot (CdCl_2)_3]^{2-}$  and two  $[WO_4(CdCl_2)_2]^{2-}$  in  $S_{11}$ ; the additional chloride ions are linked to the central metallic cation involving a eight  $S_6$ ,  $S_8$  or seven  $S_{11}$  coordinated cadmium or mercury with coordination sphere are wide enough.

#### 4 - Conclusion

The dinuclear tungstate complexes contain one bichelating tungstate anion involving three or four oxygen atoms, the trinuclear complex two bichelating tungstate anions, the tetranuclear complexes three bichelating tungstate anions, the pentanuclear complex, one trichelating and two bichelating anions, the hexanuclear complex two trichelating and one bichelating tungstate, the heptanuclear complex, three trichelating tungstate anions. Extra addition of chloride ions on the central metal occurs in some complexes.
